for each type of operation and to separate this operation implementation from the objects structure. The object structure is not likely to be changed but is very probable to have new operations which have to be added.

~~Visitor Pattern | Object Oriented Design~~

In object-oriented programming and software engineering, the visitor design pattern is a way of separating an algorithm from an object structure on which it operates. A practical result of this separation is the ability to add new operations to existing object structures without modifying the structures.

Not knowing the runtime type of the object is actually an assumption of the Visitor pattern. You can understand the pattern in two ways. The first one is that it's a trick to do multiple dispatch in a single-dispatch language. The other is that it's a way to do abstract data types in OOP languages.

Visitor design pattern is one of the behavioral design patterns. It is used when we have to perform an operation on a group of similar kind of Objects. With the help of visitor pattern, we can move the operational logic from the objects to another class. The visitor pattern consists of two parts:

The observer pattern is used to allow an object to publish changes to its state. Other objects subscribe to be immediately notified of any changes. State. The state pattern is used to alter the behaviour of an object as its internal state changes. The pattern allows the class for an object to apparently change at run-time. Strategy. The strategy pattern is used to create an interchangeable family of algorithms from which the required process is chosen at run-time.

By definition, Design Patterns are reusable solutions to commonly occurring problems (in the context of software design). Design patterns were started as best practices that were applied again and again to similar problems encountered in different contexts. They become popular after they were collected, in a formalized form, in the Gang Of Four book in 1994.

Object-oriented programming (OOP) is a programming paradigm based on the concept of "objects", which can contain data and code: data in the form of fields (often known as attributes or properties), and code, in the form of procedures (often known as methods).. A feature of objects is that an object's own procedures can access and often modify the data fields of itself (objects have a notion of ...

In object-oriented programming (OOP), a factory is an object for creating other objects - formally a factory is a function or method that returns objects of a varying prototype or class from some method call, which is assumed to be "new".
